Abstract. Online shopping in open markets becomes increasingly popular with the development of the Internet. The purpose of this study is to formulate and evaluate critical success factors in the open market from the perspective of buyers. Based on an extended technology acceptance model, this study assumes that the success of open markets are influenced by several factors, including perceived website quality, perceived usefulness, third party recognition, satisfaction, and trust. An empirical survey is conducted and questionnaires are collected from the respondents who had experience in using the open markets. The hypotheses are verified by using the structural equation modeling. Testing results are summarized and managerial implications are discussed.

Keywords: Open market, e-commerce, extended technology acceptance model, purchase intention

1 Introduction

Open markets provides consumer-to-consumer (C2C) electronic commerce on the Internet. They use online auctions, web forums, chat rooms, and third party listing. They are one of the applications that come close to emulating the success of the other two main e-commerce models, business-to-business (B2B) and business-to-consumer (B2C) [1]. Although there have been many researchers discussing the issues of transaction intention in B2C e-commerce, a few studies have attempted to explain the factors influencing the adoption of C2C e-commerce [2], and there has been a few research on the critical factors influencing C2C purchase intention in the open market. Therefore, it is necessary to conduct an analysis of which factors influence people's intention to take part in online transactions and a study on how to encourage consumers to accept C2C shopping in the open market.

The transactions in C2C e-commerce are conducted between two consumers, so it is difficult to build trust between them. A third party then plays an important role in C2C e-commerce. Under the third party's control, more users are willing to trust open markets. However, there are still many barriers, which deter users from participating in C2C e-commerce. Security of payment, trust, and privacy policies are the reasons that users are reluctant to shop online. Previous research has found differences between C2C and B2C e-commerce, pinpointing that B2C e-commerce methods have

limitation to be utilized in C2C e-commerce [3]. Consumers' purchase intention in the open market has thus proven to be a distinct area of research, and its operation requires the use of new models.

Based on Davis' technology acceptance model (TAM) [4], this study investigates which factors may influence consumers' purchase intention in the open market. Previous studies have suggested that website quality that meets consumer needs could affect consumers' purchase behavior [5]. Therefore, this study modifies TAM and proposes that perceived website quality has an effect on consumer behavior. This study also focuses on the concept of trust. Both perceived website quality and third party recognition affect consumer's trust toward the vendor. Based on these hypotheses, this study investigates the acceptance of C2C e-commerce in the open market. The remainder of the paper is organized as follows: Section 2 addresses previous relevant research and formulates research hypotheses. Section 3 describes an analysis methodology and presents empirical results. Section 4 concludes this study.

2 Research Hypothesis and Related Literature

The model proposed in the paper presents purchase intention as being influenced by direct and indirect relationships with perceived website quality, perceived usefulness, third party recognition, satisfaction, and trust.

2.1 Perceived Web Site Quality (PWSQ) and Perceived Usefulness (PU)

As Szymanski and Hise observed [6], a few studies have examined the factors that affect whether online consumers are satisfied with their online experiences. Jeong and Lambert proposed that website quality consisted of six potential dimensions: information accuracy, completeness, relevancy, clarity, ease of use, and navigation quality [7]. According to these studies, website quality can be analyzed by using two major constructs, such as functionality and usability. Functionality relates to content of a website, while usability relates to issues of design. Functionality relates to the information richness of a website, whereas usability refers to the degree of ease with which users can use a website.

Researchers have indicated that the greatest threat to e-commerce is consumer awareness. An individual's perception of the environment would affect his risk and safety assessment [8]. Even if consumers have a positive buying experience, the early concern about the atmosphere could prevent further transactions. In addition, the quality of websites related to perceived usefulness and had an effect on the user's online purchase intention [9]. The website quality was an important driver of consumer perception about the future online activity [10]. Bai et al. [11] have confirmed the relationship between website quality and satisfaction in an e-commerce environment. In addition, Everard and Galletta showed that website quality affected consumer trust in an online store [12]. Jones and Leonard's study confirmed that website quality had an impact on trust in the C2C e-commerce [3].

In an open market, a website is a medium connecting vendors and buyers. This study thus assumes that perceived website quality (PWSQ) is associated with

perceived usefulness (PU), satisfaction (SAT), and trust (TRU). The first three hypotheses are listed as follows:

- H1: PWSQ of an open market positively influences PU.
- H2: PWSQ of an open market positively influences SAT.
- H3: PWSQ of an open market positively influences TRU.

TAM has been based on the theory of reasoned action, proposed by Fishbein and Ajzen [13]. TAM predicts information technology acceptance and usage in the workplace and makes IT adoption research more efficient [4]. Its effectiveness has been revealed by numerous empirical studies. Information system usage is regarded as an important success indicator of information systems in the TAM. User satisfaction has been widely used by researchers as an alternative success indicator of information systems and as an indicator of technology acceptance. TAM suggests that perceived usefulness has a direct and significant impact on users' attitudes. Previous research has shown that perceived usefulness has a significant effect on user satisfaction in technology adoption [14] and in electronic markets [15]. Therefore, this study hypothesizes that:

- H4: PU positively influences SAT.

2.2 Third Party Recognition (TPR), Satisfaction (SAT) and Trust (TRU)

Lee and Turban presented the important relationships between consumer trust in e-commerce and three groups of antecedents: trustworthiness of the Internet merchant, trustworthiness of the Internet shopping medium, and infra-structural factors (effectiveness of third party functions, certification, and effectiveness of security) [16]. Sultan et al. demonstrated that website characteristics (navigation, brand, advice, no errors, presentation, order fulfillment, and community) and consumer characteristics (previous experiences with the Internet and with a particular website) significantly affect trust in a website [17]. Gefen et al. showed how trust and TAM were related to the purchase intention of low-risk goods from vendors [18].

In an e-commerce environment, consumers find it difficult to get comprehensive information. Especially in open markets, vendors deal with buyers as individuals, and most of the goods being traded is not expensive. Because the third party connects vendors and buyers, its recognition (reputation) is found to be a significant factor in an open market. A third party institution has been shown to reduce uncertainty the buyer feels and to increase his trust when making online transactions. McKnight et al. referred it as institution-based trust [19], which is considered as a fundamental requirement in open markets. Third party recognition affected trust in an online shopping environment [20]. In addition, third party recognition was found to be positively related to confidence of buyers and to be negatively related to purchase risk perception. Based on Jones and Leonard's study [3], perception of website quality and third party recognition influenced C2C e-commerce trust. Therefore, this study hypothesizes that:

H5: TPR positively influences TRU.

From Ajzen and Fishbein's research [21], behavior intention was found to be determined by the individual's attitude toward the behavior, and a person's attitude is affected by his beliefs. An empirical study has indicated that trust is strongly related to attitude [22]. In a buyer-seller relationship, buyer's evaluation of trust before a specific exchange is found to have a direct influence on their post-purchase satisfaction [23]. In an e-commerce situation, trust has been empirically found to be a strong predictor of satisfaction [24]. If buyers feel that vendors are trustworthy, they are more satisfied with the open market. Therefore, the following hypothesis is proposed:

H6: TRU positively influences SAT.

2.3 Purchase Intention (PI)

It is important to understand purchase intention of buyers, because their behavior can usually be predicted by their intention. Zeithaml and Parasuraman asserted that the purchase intention could be seen as a dimension of behavioural intention [25]. Purchase intention is correlated to actual behavior [21] and this relationship has been empirically tested in hospitality and tourism businesses [26]. In addition, customer satisfaction turns out to be an important factor of behavioural intention in an online business [7].

Satisfaction is a quasi-attitudinal construct and often considered as an attitude [27]. Davis suggested that users' attitudes could affect users' behavioral intention directly [4]. As a result, satisfaction has been investigated as an antecedent to the continuous intention of e-commerce services in technology acceptance [28]. Several researchers in marketing have empirically shown that satisfaction has a significant and positive effect on consumer purchase intention [29]. Information system researchers also have confirmed the relationship between satisfaction and continuous intention of e-commerce services [15]. Thus, this study advances:

H7: SAT positively influences PI.

TAM stated that perceived usefulness had a direct effect on the user's behavioral intention, because users are more willing to use technology if it can afford benefits. Perceived usefulness mediates the effect of perceived ease of use on behavioral intention. Most empirical studies have provided strong evidence that perceived usefulness directly influences users' intention of adopting new technology [30]. Several empirical studies have supported this 'perceived usefulness-user intention' connection in the open market, including He et al. [1], for example. The following hypothesis is thus proposed:

H8: PU positively influences PI.

Many researchers have indicated that trusting trading partners can sometimes increase efficiencies. The action of sharing confidential information creates a situation that may be convenient to one or both partners [31]. This suggests a need for trust. Trust plays a vital role in online business, and it is a critical antecedent of building a relationship between buyers and sellers [32]. McKnight et al. suggested that a willingness of purchase was determined by trust [19]. Gefen and Heart suggested that trust significantly influences consumers' purchase intention in an e-commerce [33]. Therefore, this study presents the last hypothesis as follows:

H9: TRU positively influences PI.

3 Analysis and Results

3.1 Characteristics of the Sample

Scales for perceived usefulness were adopted from studies of He et al. [1]. Measures for perceived website quality, satisfaction, and purchase intention were adopted from Bai et al. [11]. Measures for third party recognition and trust were adopted from Jones and Leonard [3]. All items were measured by 5-point Likert scale with anchors ranging from 'strongly disagree' (1) to 'strongly agree' (5).

The survey was conducted in Korea. Most online shopping users were between 20 and 40 years of age and more than half of them were buying on open markets (C2C websites). 177 samples were collected (81% return rate). 19 of these had no C2C experiences in the open markets, and 11 contained incomplete answers or obvious self-contradictions. As a result, 147 responses were used in continued analysis. The characteristics of the sample were as follows: Male and female responders showed even distribution. The respondents were relatively young, so that 87.1% were between 21 and 30 years old. Most of the samples (80.3%) were high school graduates, 10.2% were university graduates, and 9.5% had a higher education. 9.5% were employees. Most of the respondents (78.9%) bought goods in open markets once or twice a month and often bought goods from Gmarket.com (60.6%) and Auction.co.kr (38.8%).

3.2 Validation of Reliability and Validity

Structural Equation Modeling (SEM) was used to analyze survey data (AMOS 7.0). To assure the quality of research, reliability and validity are often considered as indicators of how good a piece of research is. While reliability is concerned with the accuracy of the actual measuring instrument or procedure, validity is concerned with the study's success at measuring what the researchers set out to measure. Cronbach's α was used for the reliability test, which is a measure of the squared correlation between observed and true scores. If α is greater than 0.7, it means that it has high reliability and if α is smaller than 0.3, then it implies that there is low reliability. All Cronbach's α values are displayed in Table 1. All values in the table are above 0.7,

which means a good level of reliability. This study then performed a confirmatory factor analysis (CFA) to evaluate the convergent validity of the constructs. The results as well as the recommended values for the measures are also shown in Table 1.

Table 1. Reliability and convergent validity.

Construct	Factor loadings	Cronbach's α (> 0.7)	AVE
PWSQ			
PWSQ1	0.917		
PWSQ2	0.943	0.860	0.881
PWSQ3	1.0		
PWSQ4	0.723		
PU			
PU3	0.708	0.785	0.660
PU4	1.0		
SAT			
SAT1	1.0		
SAT3	0.788	0.800	0.847
SAT4	0.925		
TPR			
TPR1	0.909	0.753	0.595
TPR2	1.0		
TRU			
TRU1	1.0		
TRU2	0.913	0.813	0.839
TRU3	0.760		
PI			
PI2	0.791	0.824	0.582
PI3	1.0		

Additionally, discriminant validity is shown to be good when the square root of each construct's average variance extracted (AVE) is larger than its correlations with other constructs. As shown in Table 2, the square root of the AVE (written in bold) is much larger than its correlations with other constructs.

Table 2. Inter-construct correlations and discriminant validity.

	PWSQ	PU	SAT	TPR	TRU	PI
PWSQ	0.939					
PU	0.366	0.812				
SAT	0.329	0.578	0.920			
TPR	0.281	0.338	0.386	0.772		
TRU	0.303	0.262	0.369	0.383	0.916	
PI	0.415	0.465	0.633	0.380	0.409	0.763

3.3 Path Analysis and Hypothesis Testing

The model fit the observed data well. Several model fit indexes conformed to the recommended values. NFI was marginally acceptable at 0.890 and other fit indexes were within acceptable thresholds: GFI=0.912, AGFI=0.873, CFI=0.973, RMR=0.048, and RMSEA=0.044. Fig. 1 shows the standardized path coefficients.

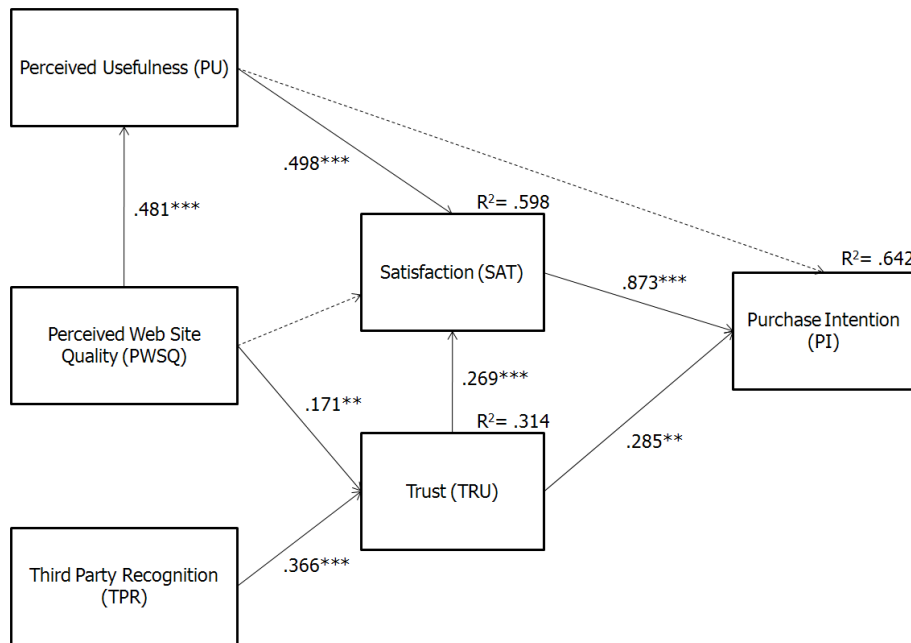

Fig. 1. Results of testing hypotheses (*: $p < 0.1$, **: $p < 0.05$, ***: $p < 0.01$).

All paths were significant except the path between perceived website quality and satisfaction ($\gamma = 0.672$, $t = 0.786$), and the path between perceived usefulness and purchase intention ($\gamma = 0.160$, $t = 1.005$), rejecting H2 and H8. The rejection of H2 is different from the findings of Bai et al. [11]. Perceived website quality has an indirect effect on consumer satisfaction through perceived usefulness. The rejection of H8 does not meet our initial expectations. Many other studies have shown that perceived usefulness has a significant and direct impact on purchase intention [1]. In this study perceived usefulness can be found to have an indirect effect on purchase intention only through satisfaction.

The effect of perceived website quality on perceived usefulness ($\beta = 0.481$, $p < 0.01$) and trust ($\beta = 0.171$, $p < 0.05$) were significant, validating H1 and H3. The adoption of H1 is consistent with the findings of Liao et al. [10] who verified the significant relationship between perceived website quality and perceived usefulness from the perspective of consumers. The website quality (including color, language, goods information, and transaction system quality) can affect consumers' perceived

usefulness. The better quality can make consumers feel that the website is useful to their shopping activity. There are several studies showing that perceived website quality has an effect on trust [3][10]. Website quality can enhance the confidence of buyers toward the vendor. When websites are easy to use and they are filled with quality, buyers would like to depend on the vendor to trust them.

Perceived usefulness was found to influence satisfaction ($\beta = 0.498$, $p < 0.01$), supporting H4. Previous studies indicated that perceived usefulness significantly influenced consumer satisfaction in online shopping [15]. When consumers feel using open markets can save their time and money, they certainly will be satisfied with C2C shopping. The effect of third party recognition on trust ($\beta = 0.366$, $p < 0.01$) was shown to be significant, validating H5. This is consistent with the findings of Jones and Leonard [3]. In open markets, third parties play an important role in dealing, so the third party's reputation seems to reduce uncertainty between buyers and vendors.

The effect of trust on satisfaction was also significant ($\beta = 0.269$, $p < 0.01$), validating H6. This result is consistent with the findings of Kim et al. [34], who presented trust had a significant and positive impact on consumer satisfaction. If consumers think a vendor is trustworthy and the information provided by the vendor is reliable, they will feel more satisfied with the open market. Satisfaction ($\beta = 0.873$, $p < 0.01$) was the strongest predictor of purchase intention, followed by trust ($\beta = 0.285$, $p < 0.05$), supporting H7, H9. The adoption of H7 confirms the findings of Bai et al. [11]. When consumers are satisfied with the open market and feel it is a good place to trade, they will be willing to participate in C2C transactions. The acceptance of H9 meets the findings of Gefen and Straub [35], which were based on the B2C environment.

4 Conclusions

This study has developed and empirically tested a theoretical model of C2C online shopping adoption in the open market. The results validated that C2C purchase intention was determined by perceived website quality, perceived usefulness, third party recognition, satisfaction, and trust. The results supported seven hypotheses.

The hypothesis-testing results showed perceived website quality significantly affected user perception of usefulness and trust. Therefore, online businesses that run open markets on the Internet should develop several capabilities including convenient transaction information search, easy transaction methods, and fast system access, to improve the perception of usefulness and trust. However, the results showed that perceived website quality did not significantly contribute to consumer satisfaction. A possible explanation is that satisfaction in the open market depends on transaction experiences, which are the most noticeable uncertainty related to trust, because users may overlook website quality.

The results also showed that perceived usefulness did not affect purchase intention. A possible explanation is that the responders in this study were consumers who have had several purchase experiences in open markets. Since they know that there are risks involved in C2C e-commerce, low price may be the only factor to influence new users' purchase intention. However, perceived usefulness was still an important issue

related to purchase intention and the findings showed perceived usefulness influenced purchase intention indirectly through satisfaction. Third party recognition seems to have a significant effect on trust. This means that consumers in this study did care about third parties, their reputation, vendor evaluation system, and the number of successful transactions.
